src/__init__.py

The package marker that makes `src` importable

This file is what turns the **src** folder into an importable Python package. It contains only a docstring, but its mere presence lets every other part of the project write **from src import ...**. There is no executable code here on purpose.

Walkthrough of all 6 lines, in order. Left numbers are the real line numbers in the file.

```
1  """Agentic RAG research assistant — source package.
2
3  The single source of truth for the project. `run_pipeline.py`, `run_eval.py`,
4  `ask.py`, the notebooks, and the tests all import from here; nothing
5  re-implements retrieval, chunking, or generation a second time.
6  """
```

Lines 1 to 6 are the package docstring. A string literal placed as the very first statement in a package's __init__.py becomes the package's documentation, readable via help(src). The text states the project's guiding rule: this package is the single source of truth, and the entry-point scripts, notebooks, and tests all import from it rather than re-implementing retrieval, chunking, or generation. Because the file has no imports or statements, importing src is instant and free of side effects.
